

Consider an ideal monatomic gas, which means $U = \frac{3}{2}Nk_B T$ and $pV = Nk_B T$. The number of gas molecules N is constant.

Missing /var/www/paradigms_media_2/media/activity_media/triangle-engine_GI40pn0.pdf

Find the efficiency of this gas cycle as a heat engine, and compare to the Carnot limit.

For this question, the specific value of N doesn't matter.
