

Discuss at your table:

1. Were groups in agreement about the magnitude  $|Y|$  and the phase  $\phi_I$  response of the circuit's response (admittance)?
2. What features of the data are reasonably described by the model we studied in class?
3. What features are not? Are these model deficits or experimental data acquisition problems?
4. What physics is still not well understood by people at your table? (Most people? Some people? One person?)
